2000**

This report includes the most commonly used U.S. Department of Agriculture, Forest Service, Forest Inventory and Analysis (FIA) statistics. Additional forest resource data can be obtained through FIA staff, an FIA CD-ROM disc, or a table generator on the North Central Research Station's Internet page. Persons requesting additional information from FIA staff are expected to pay the retrieval costs. Requests may be directed to:

FOREWORD

FIA is a continuing endeavor as mandated by the Renewable Resources Research Act of 1978, the Forest Ecosystems and Atmospheric Pollution Act of 1988, and Section 253(c) of the Agricultural Research, Extension, and Education Reform Act of 1998. The objective of FIA is to inventory the Nation's forest land. Up-to-date resource information is essential to frame forest policies and programs. USDA Forest Service regional research stations are responsible for conducting these inventories. Fieldwork for the fourth forest inventory of Illinois was begun in August of 1996 and completed in August of 1998. Reports of previous inventories of Illinois are dated 1948, 1962, and 1985. The State of Illinois provided valuable cooperation and assistance throughout the course of this most recent inventory effort.

Notice to users of the 1998 inventory of Illinois's forest resources results:

Tables in the appendix relating to sawtimber volume are presented in both International 1/4 inch rule and Doyle rule. International 1/4 inch rule is the USDA Forest Service standard while Doyle is the common measure used in Illinois by forest industries and land management agencies. Because these results are used nationally and consistent comparisons are crucial, International 1/4 inch rule is used as the unit of measure for sawtimber volume unless Doyle rule is noted in the text. We have made an effort to include Doyle tables and discussion where appropriate to improve the utility of the inventory results for regional and local users of these results.

Data from new inventories are often compared with data from earlier inventories to determine trends in forest resources. However, for the comparisons to be valid, the procedures used in the two inventories must be similar. As a result of our ongoing efforts to improve the efficiency and reliability of the inventory, several changes in procedures and definitions have occurred since the last Illinois inventory in 1985. Because some of these changes will make it inappropriate to directly compare the 1998 data with those published for 1985, data from the 1985 inventory have been reprocessed using the 1998 procedures. Please refer to the section labeled "Comparing the fourth inventory of Illinois with the third inventory" in the appendix for more details.

Perhaps the most significant change between inventories was the development of new volume tables between the 1985 and 1998 inventories of Illinois' forest resources. The new volume tables, developed by USDA Forest Service research scientists and other cooperating researchers, more accurately estimate the true growing-stock and sawtimber volume. In general, the old volume tables used in the previous inventories slightly overestimated the true volume. As a part of the current inventory, we updated the 1985 inventory using the new volume tables. As a result, the volumes that were recalculated for the 1985 inventory show a small decrease from the previously published volumes (Resource Bulletins NC-103 – Illinois Forest Statistics, 1985, and NC-105 – Illinois' Forest Resource). All tables with 1985 data, and comparisons to the 1985 inventory results, in this publication reflect the recalculated volumes.

Field work for this most recent inventory was completed between 1996 and 1998. All data related to area and volume are dated 1998. Because field measurements were ongoing during 1998 and change data such as growth, mortality, and removals continued to occur in 1998, these data are dated

1997. Comparisons between the most recent inventory and updated previous inventories for area and volume compare 1985 with 1998. Comparisons for growth, mortality, and removals compare 1985 with 1997.

FIA St. Paul, Minnesota, staff involved in the fourth inventory of Illinois included Beth Collins, Dave Frazier, Barb Fuller, Dale Gormanson, Ron Hackett, David Haugen, Barb Knight, Leo Larkin, Earl Leatherberry, Dennis May, Pat Miles, Tim Miller, Jerry Ostrom, Ron Piva, Gerhard Raile, Mary Jo Resendez, Tyson Schreiner, and Dan Wendt. FIA field staff involved in this inventory were Ryan Anderson, Joseph Boykin, Steve Fadden, Tom Forbes, Cheri Hartless, Patrick Hartless, Glenda Hefty, Bryan Hendricks, Gary Inhelder, Brian Peura, Brad Witkin, and Erin Witkin.

Illinois' Forests in 1998

Thomas L. Schmidt, Mark H. Hansen, and James A. Solomakos

Illinois has a variety of forest resources that make significant environmental and economic contributions. In addition to employment and other economic contributions, Illinois' forests provide outdoor recreation experiences as well as improve and protect the State's soil and water resources. The State is divided into three Survey Units, based largely on topography and location of forest land (fig. 1).

HIGHLIGHTS

- The area of Illinois' forests continued to show a net increase between inventories, a trend that began in the 1960's. The primary causes were increases in the width of existing narrow wooded strips and the conversion of cropland and pasture to forest land. These increases were greater than losses by development of forest land for agriculture, urban/suburban expansion, and other uses.
- Net growth exceeded harvest in Illinois. Average annual net growth of growing stock exceeded the average annual harvest by a 2.6 to 1 margin between 1985 and 1997. As a result of the expanding resource and the greater growth than harvesting, the volume of trees growing in Illinois continued to increase.
- During the 13 years between inventories, an average of 21.8 million new growing-stock trees were established each year in Illinois. As a result, in 1998 there were 283.7 million more growing-stock trees than in 1985.
- The future of the forest lies in the hands of individual private landowners. They own almost 90 percent of the total area of timberland in Illinois.

Thomas L. Schmidt and **Mark H. Hansen** are Research Foresters, and **James A. Solomakos** is a Computer Programmer Analyst, in the Forest Inventory and Analysis Program at the North Central Research Station, St. Paul, Minnesota.

EXTENT OF ILLINOIS' FORESTS

- Area of forest land and timberland has increased since the 1960's (timberland is a subset of forest land; timberland has minimum productivity capabilities and is not permanently excluded from harvest by legislation or administrative order). Due to the dominance of timberland, the majority of this report presents results related to timberland. Timberland has historically represented more than 90 percent of the total area of forest land in Illinois. For example, of the 4.3 million acres of forest land in 1998, 94 percent was classified as timberland.
- The area of timberland in Illinois has been steadily increasing since the 1960's. Timberland increased from 3.981 million acres in 1962, to 4.030 million acres in 1985, to 4.087 million acres in 1998 (fig. 2). In 1998, timberland represented 11 percent of the total land area in Illinois.
- The majority of the increase in area of timberland between 1985 and 1998 occurred in the Southern Unit. The Claypan Unit slightly increased while the Prairie Unit slightly decreased in area of timberland.
- Pope County, in the Southern Unit, was the most heavily forested county in both 1985 (143 thousand acres of timberland) and in 1998 (151 thousand acres of timberland).
- In 1998, the Southern Unit was the most heavily forested Survey Unit with almost 3 out of every 10 acres classified as timberland. Conversely, in the Prairie Unit, less than 1 out of every 10 acres was classified as timberland. The Prairie Unit was the most urbanized and agriculturally oriented part of the State. In the Claypan Unit, 15 percent of the total area of land was classified as timberland.
- Individual private landowners were the largest timberland ownership group in Illinois, owning 82 percent of all timberland in 1998. The Federal government was the

Figure 1.—Forest land as a percent of land area by county, and Survey Unit, Illinois, 1998.

Figure 2.—Area of timberland in Illinois by inventory time period.

largest public owner of timberland with 313 thousand acres, representing 8 percent of the total timberland area.

COMPOSITION OF ILLINOIS' FORESTS

Area

- Illinois' forests were predominately hardwoods with 97 percent of the total area of timberland classified as hardwood forest types. The primary hardwood forest types in Illinois were oak/hickory with 2.1 million acres, elm/ash/cottonwood with 906 thousand acres, and maple/beech with 696 thousand acres (fig. 3).

Figure 3.—Area of timberland in Illinois by selected forest types, 1985 and 1998.

- In 1998, conifer forest types represented only 3 percent of the total area of timberland in Illinois. In 1998, there were 47 thousand acres where eastern redcedar was the predominant species and 63 thousand acres where pines were the predominant species.
- Between 1985 and 1998, the area of short-leaf pine, oak/pine, and maple/beech declined. The area of oak/hickory remained stable while the area of white pine, eastern redcedar, oak/gum/cypress, elm/ash/cottonwood, and cherry/ash/yellow-poplar all increased between 1985 and 1998.
- Increases in the area of eastern redcedar occurred as nonforest land with trees in 1985 increased its stocking level by 1998 through increases in total number of trees and in the diameter size of existing trees, which resulted in these stands now being classified as timberland. In previous inventories, elm/ash/cottonwood bottomland forests existed as narrow wooded strips but did not meet the minimum requirement for timberland (at least 120 feet in width). Over time, these narrow forests expanded in width to where, by 1998, they qualified as timberland, which contributed to the overall statewide increase in timberland. Increases in the area of cherry/ash/yellow-poplar occurred as selective harvesting and natural mortality caused timberland stands that were classified as either oak/hickory or maple/beech in 1985 to be reclassified as cherry/ash/yellow-poplar in 1998.
- Between inventories, the area of poletimber-size and sawtimber-size stands increased as Illinois' forests continued to mature and increase their average diameters (fig. 4). Diameters are measured at 4.5 feet above ground and are referred to as diameter at breast height (d.b.h.). As the area in larger stands increased, the area in sapling-seedling-size stands decreased. This change occurred as sapling-seedling-size trees measured in 1985 increased their diameters through growth to where, by 1998, they qualified as either poletimber or sawtimber-size trees. In 1985, sawtimber-size stands accounted for 64 percent of the total area of timberland. However, by 1998, sawtimber-size stands represented 72 percent of the total area of timberland.

Figure 4.—Area of timberland in Illinois by stand-size class, 1985 and 1998.

- The increase in the average stand-size class in Illinois between inventories is an indication of a lack of significant disturbance through either natural occurrences or harvesting. Selective harvesting methods used in hardwood stands throughout the Central Hardwood Region do not cause the large-scale disturbances that are needed to reclassify the timberland as sapling-seedling-size stands. Sixty-five percent of the new forest land (areas classified nonforest in 1985 and forest in 1998) was classified sawtimber in the 1998 inventory. This occurred through the expansion of narrow wooded strips and other small wooded areas that had trees but were not classified forest in 1985 because they were too narrow (less than 120 feet wide) or too small in area (less than 1 acre in size) and by the expansion of existing forest land into other nonforest areas.
- In 1998, 40 percent of the timberland in Illinois was considered fully stocked (fig. 5). Stocking is a measure of how well-occupied the land is by trees. The goal of most forest managers is to maintain the forests in a fully stocked condition since this condition provides for optimal growth. There are opportunities to improve the current growth rate and the overall health and vigor of Illinois' timberlands.
- The average potential productivity of timberlands in Illinois is above the national average. Potential productivity is an estimate of the volume growth per acre per year

Figure 5.—Area of timberland in Illinois by stocking class, 1998.

at culmination of mean annual increment of a fully stocked stand. Although this definition is intended for industrial wood production, it is a good measure of the potential of a forest to produce a wide array of products and benefits. In Illinois, half of the total area of timberland has the potential to produce more than 85 cubic feet of wood per acre per year (fig. 6). As a comparison, 29 percent of Michigan's timberlands have a potential productivity of more than 85 cubic feet per acre per year (Schmidt *et al.* 1997).

Number of Trees

- In terms of the total number of growing-stock trees, elm with more than 412 million trees was the most abundant species group

Figure 6.—Area of timberland in Illinois by potential productivity class, 1998.

in Illinois in 1998. Other species groups with more than 100 million trees included hickory, red oak, sugar and black maples, ash, hackberry, and black cherry. Eastern redcedar, with almost 20 million growing-stock trees in 1998, was the most abundant conifer.

- The number of growing-stock trees in Illinois increased from 1.6 billion in 1985 to 1.9 billion in 1998. Illinois had an estimated population of 12 million people in 1998, so there were almost 160 growing-stock trees for each citizen in the State.
- Between 1985 and 1998, elm, sycamore, willow, hackberry, black cherry, black walnut, and yellow-poplar all increased in the total number of growing-stock trees by at least 25 percent.
- Due to the high economic and wildlife benefits associated with oaks, they are of special concern in Illinois. Between 1985 and 1998, the total number of trees in the red oak species group increased by 30 percent and the total number of trees in the white oak species group decreased by 12 percent.
- In addition to white oak, basswood, beech, soft maple, cottonwood, river birch, and butternut all decreased in the total number of growing-stock trees between 1985 and 1998.

Growing-stock Volume

- Growing-stock volume increased from 4.7 billion cubic feet in 1985 to 5.9 billion cubic feet in 1998, reflecting the increase in both area and stocking during the 13 years between inventories. This increase continued the trend in Illinois of increasing growing-stock volume with each new inventory (fig. 7).
- With the increase in total growing-stock volume, average timberland volume per acre also increased. Average volume per acre increased from 865 cubic feet per acre in 1962 to 1,454 cubic feet per acre in 1998. The increasing level of growing-stock volume per acre in Illinois reflects increasing stocking rates and high “growth to removals” ratios. If stocking could be increased,

Figure 7.—Total growing-stock volume in Illinois by inventory time period.

average volumes would be expected to continue to rise, allowing for increased harvesting and other uses without threatening the resource.

- Growing-stock volume increased between inventories in all three units (fig. 8). While the Prairie Unit had the most total growing-stock volume, it had the lowest average growing-stock volume per acre with 1,374 cubic feet per acre. The Southern Unit averaged 1,528 cubic feet per acre and the Claypan Unit averaged 1,487 cubic feet per acre. On average, the higher the average volume per acre the higher the stocking rate.

Figure 8.—Growing-stock volume in Illinois by unit, 1985 and 1998.

- Sawtimber volume also increased in Illinois between 1985 and 1998, rising from 16.2 billion board feet in 1985 to 21.9 billion board feet in 1998 (International 1/4 inch rule). The increase in growing-stock and sawtimber volume shows the dominance of Illinois' timberland by larger stands and trees. As these forests mature, it could be expected that future regeneration might favor shade-tolerant species. As a result, future regeneration of shade-intolerant species might be expected to decline.
- In both 1985 and 1998, hardwoods accounted for 97 percent of all growing-stock volume. The species groups with the most growing-stock volume in 1998 were red oaks, white oaks, soft maple, hickories, ash, cottonwood, and hard maple (all with more than 200 million cubic feet) (fig. 9).
- In 1998, 87 percent of the total volume of timber in Illinois qualified as growing stock. In addition to growing-stock volume (5.9 billion cubic feet), Illinois had additional non-growing-stock volume in cull trees of 757 million cubic feet (short-log, rough, and rotten trees) and in salvable dead trees of 106 million cubic feet in 1998. In total, Illinois had 6.8 billion cubic feet of volume in 1998. While the vast majority of wood harvested is from growing stock, these other sources of volume also contribute to the overall harvest and availability of wood fiber in Illinois.

Figure 9.—Growing-stock volume in Illinois by selected species groups, 1985 and 1998.

Sawtimber Volume

- In 1998, sawtimber volume in Illinois totaled 21.9 billion board feet measured with the International 1/4 inch rule. Due to State and local interest, the following sawtimber volume discussions are presented using Doyle rule. To convert from Doyle rule to International 1/4 inch rule, please see the appendix for conversion factors. In the appendix tables, sawtimber volume is presented in both Doyle and International 1/4 inch rule.
- Overall, the sawtimber volume measured using Doyle is about 65 percent of the same sawtimber volume measured using the International 1/4 inch rule. The trends expressed in our discussion of sawtimber volume using the Doyle rule hold true for International 1/4 inch rule as well.
- In 1998, Illinois had 14.8 billion board feet (Doyle) of sawtimber volume. Of the total sawtimber volume, 41 percent was in trees with diameters of more than 21 inches.
- The species groups with the most sawtimber volume include red and white oak, soft maples, hickory, cottonwood, sycamore, and ash. All of these species groups had more than 600 million board feet (Doyle) of sawtimber volume.
- Between 1985 and 1998, all species groups increased their sawtimber volume except tupelo. The greatest percentage increase in sawtimber occurred in the conifers, soft maple, sweetgum, black walnut, hackberry, black cherry, and willow species groups. All these species groups increased their total sawtimber volume by at least 50 percent between inventories (fig. 10).
- Both the Claypan and Prairie Units rose by almost 1.4 billion board feet (Doyle) in the 13 years between inventories for an average annual increase of about 100 million board feet (Doyle) in each unit.

Quality of Sawtimber

- The quality of Illinois' sawtimber has improved since 1985. As an example, the percentage of sawtimber in the highest quality classifications (grades 1 and 2)

Figure 10.—Sawtimber volume in Illinois by species group between 1985 and 1998 (Doyle).

increased from 28 percent in 1985 to 48 percent in 1998 (fig. 11). The predominant reason for this improvement in quality was the increase in the overall size (diameters and lengths) of the sawtimber resource.

CAUSES OF CHANGE IN ILLINOIS' FORESTS

- The primary causes of change in Illinois' forests are natural successional processes, growth, mortality, and other natural disturbances; and human-induced changes such as harvesting and land-use change. These change factors often result in reclassifications from one forest type to another. For example, some timberland sites were classified as oak/hickory forest type in 1985. However, when our field crews re-visited these same sites in 1998, either succession had progressed to where the oak/hickory trees were replaced by other species or harvesting had occurred that changed the species composition. If oak trees are harvested and if the advanced regeneration consists of other species, the stand often converts to a different species composition, which can result in its being classified as a

different forest type. For example, in 1985, there were 2,139 thousand acres classified as oak/hickory forest. In 1998, there were 2,137 thousand acres classified as oak/hickory forest. However, not all of the 1985 oak/hickory forests stayed as this same type during the 13 years between inventories. Of the oak/hickory acreage in 1985, 1,735 thousand acres stayed in the oak/hickory forest type, 149 thousand acres were reclassified as nonforest, 136 thousand acres were reclassified as maple/beech, and the other 119 thousand acres were reclassified into other forest types. Table A shows the FIA-determined changes in land-use classification between 1985 and 1998.

- Most of Illinois' forests were not planted and are more or less naturally occurring. Less than 3 percent of the total timberland area consists of plantations where planted trees form a portion of the stand. Shortleaf pine, eastern white pine, and red pine are the major species that have been planted over the years in Illinois. Most of the timberland area in pine and oak/pine forest types are plantations. Plantations made up 100

Figure 11.—Percentage of sawtimber volume in Illinois by grade in 1985 and 1998.

percent of the white pine type, 90 percent of the shortleaf/Virginia pine type, and 60 percent of the oak/pine type area. These three forest types made up more than 75 percent of the total plantation area found in the State. In hardwood types, less than 1 percent of the timberland area was found to be in plantations. This may underestimate hardwood planting somewhat because in older hardwood forests it is often difficult to determine whether or not the stand was planted. Hardwood species that have been planted and were found in this inventory included tulip poplar, sweetgum, sycamore, black walnut, white oak, white ash, green ash, and hybrid poplar. Other species have been planted, but, either the sampling intensity of this inventory (approximately one plot per 3,200 acres of forest land) missed them or they were present on plots but not identified as planted trees.

- Illinois' forest composition has shifted over time. Timberlands that moved into nonforest land classifications represent a conversion of timberland into other land uses such as developed land (housing, road construction, and other human-induced land developments) and agriculture. In the 13 years between inventories, 441 thousand acres of timberland in Illinois were converted to nonforest land uses. During the same time period, 507 thousand acres of nonforest land converted to timberland.

- New timberland area in Illinois came primarily from nonforest lands that were reclassified into elm/ash/cottonwood, oak/hickory, and maple/beech forest.
- Between 1985 and 1998, thousands of acres of timberland were reclassified into other forest types in Illinois. These acres stayed as timberland but were reclassified because the species composition changed between inventories. Changes in species composition occur as the forest matures; natural disturbances such as windstorms and floods occur; and human-induced activities such as harvesting, timber stand improvement (TSI), and tree planting happen. These events change the composition of the forest and the resulting forest type classification.
- Timberlands undergo successional changes in species composition as natural regeneration replaces existing overstory trees. Overstory trees are lost through both natural mortality and harvesting. In Illinois, trees that replace the lost overstory arise primarily from natural regeneration. In addition, expansion of timberlands over time and increased stocking rates have occurred due to increased regeneration. Regeneration is generally considered to be in three classes of saplings/seedlings: seedlings less than 1 inch d.b.h., saplings from 1- to 2.9-inches d.b.h., and saplings

Table A... Land-use classification changes in Illinois, 1985-1998

¹ Read across rows to determine dispersion of 1985 classes to 1998 classes. Read down columns to determine origin of 1998 classes.² Total land area adjusted to conform to 1980 census figures.

To use Table A: for example, to find out what happened to the 2,139 thousand acres of oak/hickory in 1985, simply read across the oak/hickory row and find that about 1,735 thousand acres stayed as oak/hickory, 136 thousand acres were reclassified as maple/beech, 96 thousand acres were reclassified as nonforest with trees, and so on.

To determine the source of the 2,137 thousand acres of oak/hickory in 1998, read down the oak/hickory column. Of these acres, 1,735 thousand acres were classified as oak/hickory in both inventories, 211 thousand acres were reclassified from maple/beech to oak/hickory, and so on.

from 3- to 4.9-inches d.b.h. Overall, Illinois' growing-stock regeneration, expressed in number of smaller trees, has consistently increased since the 1960's (fig. 12).

Figure 12.—Total regeneration in Illinois by diameter class, by inventory period.

- Grazing by domestic animal stock can have a major impact on a forest, significantly impacting regeneration, understory vegetation, species composition, water quality, tree growth, and tree mortality. In 1998, 11 percent of the total area of timberland in the State was also being used for pasture (461 thousand acres of pastured timberland out of the statewide total of 4,087 thousand acres of timberland). These pastured timberlands are productive forest lands that have at least the minimum stocking to be classified as forest land but where domestic livestock are actively being grazed. In addition to these pastured timberlands, there are 88 thousand acres of wooded pasture and 127 thousand acres of pasture with trees in the State. These two classes have some trees, but they do not have enough stocking to be classed as forest land. They are typically more heavily grazed or have been grazed for longer periods of time than pastured timberland; as a result, there is little or no advanced regeneration or other understory vegetation and the growth on the overstory trees is being affected. Between 1985 and 1998,

grazing decreased on timberland from 14 percent of the area to 11 percent and the area of wooded pasture decreased from 162 thousand acres to 88 thousand acres. This indicates that less forest land is being used for grazing, but, much of the State's forests are still being impacted by grazing.

- Because of the maturing of Illinois' forests, and white and red oak's limited ability to regenerate under shade, the regeneration of these species is of concern. The total number of growing-stock white oak trees in both the 1- to 2.9- and 3- to 4.9-inch d.b.h. size classes declined between 1985 and 1998. As a comparison, the number of growing-stock white oaks in the 1- to 2.9-inch d.b.h. class in Indiana rose from 19.9 million trees in 1986 to more than 23.6 million in 1998.
- The total number of growing-stock red oak trees in both the 1- to 2.9- and 3- to 4.9-inch d.b.h. size classes increased between inventories (fig. 14). The number of red oaks 1- to 2.9-inches in d.b.h. increased by 73 percent and the number of red oaks 3- to 4.9-inches in d.b.h. increased by 13 percent from 1985 to 1998. As a comparison, the total number of growing-stock red oak trees in the 1- to 2.9-inch d.b.h. class in Indiana declined by 16 percent between the two most recent inventories. Thus, while the decline in small white oaks is of crucial importance, the recent increase in small red oaks helps to alleviate some of the concerns.

Figure 13.—White oak regeneration in Illinois by diameter class, 1985 and 1998.

Figure 14.—Red oak regeneration in Illinois by diameter class, 1985 and 1998.

- Between 1985 and 1997, Illinois' average annual net growth of growing stock was 175 million cubic feet. This equates to an average annual net growth rate of 43 cubic feet of growing stock per acre for each of the 4.1 million acres of timberland in Illinois. Net growth rates are gross growth minus mortality.
- Hardwoods accounted for 97 percent of Illinois' total average annual net growth. Hardwood species with the largest average annual net growth of growing stock were red oak, white oak, hickory, soft maple, elm, and ash. All these species groups averaged at least 10 million cubic feet of growing-stock annual net growth between inventories.
- Illinois' average annual mortality of growing stock was 73 million cubic feet between 1985 and 1997. This equates to an average annual mortality rate of 18 cubic feet of growing stock per acre for each of the 4.1 million acres of timberland in Illinois. With an average annual mortality rate of 18 cubic feet per acre and a net growth rate of 43 cubic feet per acre, Illinois averaged a gross growth rate of 61 cubic feet per acre between inventories (gross growth equals net growth plus mortality). If mortality can

be decreased through increased management, the additional growth could be available for harvest or other uses. However, mortality can also be positive because it provides coarse woody material for Illinois' riverine water systems and a variety of wildlife habitats.

- Between 1985 and 1997, the greatest total mortality occurred in red oak, elm, white oak, ash, hickory, and cottonwood. Elm mortality was primarily due to Dutch elm disease. Mortality of other species was due to a combination of old trees reaching the end of their lifespan, natural competition with other trees, flooding, and a variety of diseases and insects.
- Between 1985 and 1997, Illinois' average annual removals of growing stock were 67 million cubic feet. This equates to an average annual removal rate of 16 cubic feet of growing stock per acre for each of the 4.1 million acres of timberland in Illinois. This removal rate represents 1.1 percent of the total growing-stock volume in Illinois.
- About 30 percent of the total average annual removals from timberland were due to land-use change. This included timber cut during land-use change such as in conversion to cropland and lands that have been lost from timberland to other land-use classes where the trees may not have been cut. Much of the removals in State and National Forest ownership shown in table 24 were due to land-use change. Examples of public land-use change include the conversion of timberland to reserved forest land (such as when State-owned land that was available for harvest in the previous inventory is now a State Park); and marsh with trees (due to natural and/or artificial increases in water levels). Of the observed average annual 1.4 million cubic feet of growing-stock removals on State land, 0.3 million cubic feet were found on lands being added to State Parks (and thus "removed" from the timberland base) and 0.9 million cubic feet were on forest land that became marsh with trees between inventories (also removed from the timberland base). Because removals (due to harvesting and land-use change) are an uncommon event on

State and Federal lands, estimated removals for a particular ownership group can have large sampling errors because they are based on observations of only a few field plots. As a result, we encourage you to consult table 56 for the sampling errors and read the sampling error discussion in the appendix when using results related to removals.

- The removal rates, as a percent of total growing-stock volume by unit, were Southern 1.3 percent, Claypan 1.1 percent, and Prairie 1.1 percent. Limiting factors in the Prairie Unit regarding timber utilization for wood fiber are the distances that harvested logs have to travel for processing, a different species composition, and the small average ownership tract size compared to other units. The majority of the wood fiber industry in Illinois is in the southern portions of the State. As a result, only high-quality trees in northern Illinois warrant the additional travel costs associated with harvesting. There are opportunities to increase the number of portable sawmills because they can move to the trees rather than having the trees move to the processing facilities.
- The average annual removal rate for hardwood growing stock (66 million cubic feet) was 1.1 percent of the total hardwood growing-stock volume. Average annual removals of conifer growing stock were 1 million cubic feet, 0.6 percent of the total softwood growing-stock volume.
- Average annual net growth was more than double the average annual removal rate statewide and in all units (fig. 15). All units have an opportunity to increase their harvest rates without threatening long-term sustainability. In localized regions, removal rates are higher than the unit average. In these regions, removals for wood fiber industries might have to expand into broader drain areas, but wood fiber will be available based on the growth-to-removal ratios. Opportunities for expansion of wood fiber-based industries appear strong in all three units based on average annual net growth rates compared to average annual removal rates.

Figure 15.—Average annual net growth and removals for hardwoods in Illinois by unit between 1985 and 1998.

- Between 1985 and 1997, the primary species groups harvested (growing-stock removals) in Illinois were red oak, white oak, hickory, soft maple, ash, and sycamore. All these species groups averaged at least 3 million cubic feet of growing stock harvested each year between inventories.
- Illinois has the potential to increase its harvest rates over time due to the current growth-to-removals ratios and due to the large volume of wood fiber that currently exists in the State. For the past 30 + years, Illinois has been growing more wood fiber than what it has removed. Similar to putting money in the bank for future use, this “banked” wood fiber is available for future harvesting.
- With strong growth-to-removals ratios, increasing area of timberland, increasing total number of trees, increasing growing-stock volume, and strong overall regeneration rates, Illinois’ citizens should be optimistic about the future for their forests. A primary goal for the future would be to ensure the continuation of these trends.

APPENDIX

PUBLIC ACCESS TO FIA DATA

The data collected in both the 1985 and 1998 Illinois inventories used to compile the resource tables presented in this bulletin can be easily accessed. Data can be obtained over the Internet by accessing the North Central Research Station website (<http://www.ncfes.umn.edu/links.html>) and clicking on the Databases and Analysis Tools button. Data from the inventories of every State used to develop the 1997 Resources Planning Act (RPA) assessment can also be accessed at this site. Three independent databases are maintained at this site: the National FIA Database, the National Resources Planning Act (RPA) Inventory Database, and the National Timber Products Output (TPO) RPA Database. Because 1998 Illinois inventory data were not available at the time of the 1997 RPA assessment, data from the 1985 Illinois inventory were used to represent Illinois in the RPA inventory database.

The National FIA Database contains data from the previous and current ground plot based inventories, which were used to produce the majority of the estimates in this report. This includes all estimates of area; number of trees; volume; biomass; average annual net growth, mortality, and removals; and current net growth and mortality. Data are stored so that users can download portions of the database onto their own computers and produce their own estimates, or they can use an on-line table generation program to create user-specified tables similar to those presented in this report. This database is described in Hansen *et al.* (1992) and is also documented on-line. Copies of the database and a table generation program are also available on a CD-ROM. This disc can be obtained from the Program Manager, FIA, North Central Research Station, 1992 Folwell Avenue, St. Paul, MN 55108, (651) 649-5139.

The National RPA Inventory Database contains data from all States and represents a "point-in-time" inventory. Illinois inventory results

contribute to this database. RPA inventories are conducted on a 10-year cycle with mid-cycle updates every 5 years. RPA inventories differ from FIA inventories in that historically FIA inventories have been periodic and based on the year of completion of field work for any individual State. Results are published as soon as possible after the field work results are compiled and analyzed. RPA inventories use the FIA inventory results and update them to a common year. The most recent RPA inventory represents the FIA inventories of all 50 States, updated to the common year of 1997. Results are published on a regular cycle.

The National TPO RPA Database contains the data from a series of independent surveys of sawmills, pulp mills, fuelwood consumers, and other primary timber users summarized for 1996. This database was used to produce estimates of current annual removals. Users of this database can access a table generation program and obtain estimates of the current timber removals presented as well as current timber removals for other years and other States. May (1998) describes the NCFIA TPO Database, which was used to provide our input to the National TPO RPA Database.

ACCURACY OF THE 1998 ILLINOIS SURVEY

FIA information is based on a sampling procedure designed to provide reliable statistics at the State and Survey Unit levels. Consequently, the reported figures are estimates only. A measure of reliability of these figures is given by sampling errors (table B). Sampling errors for area, volume, growth, and removals, for both growing stock and sawtimber, in Illinois are shown in table 56. Sampling error means that the chances are two out of three that if a 100-percent inventory had been made (one sample plot at every point in the State), using the same methods, the results would have been within the limits indicated.

Table B.—*Sampling error for the 1998 inventory of Illinois's forests*

Item	State totals	Sampling error
Forest land	Thousand acres	Percent
Forest land area (1998)	4,331.3	1.49
Timberland area (1998)	4,087.0	1.61
All live	Million cubic feet	
Volume (1998)	6,700.3	2.18
Current net growth (1998)	201.3	1.99
Current mortality (1998)	118.8	3.11
Average annual net growth (1985-1997)	217.5	2.16
Average annual mortality (1985-1997)	107.3	3.22
Average annual removals (1985-1997)	80.6	10.05
Growing stock	Million cubic feet	
Volume (1998)	5,942.9	2.28
Current net growth (1998)	170.2	2.09
Current mortality (1998)	92.4	3.14
Average annual net growth (1985-1997)	174.5	2.45
Average annual mortality (1985-1997)	73.5	3.42
Average annual removals (1985-1997)	66.9	10.09
Sawtimber (International 1/4 inch rule)	Million board feet	
Volume (1998)	21,875.4	2.57
Current net growth (1998)	512.2	2.47
Current mortality (1998)	302.4	3.70
Average annual net growth (1985-1997)	663.6	2.63
Average annual mortality (1985-1997)	194.6	4.42
Average annual removals (1985-1997)	259.5	10.57

For example, the estimated growing-stock volume in Illinois in 1998, 5,942.9 million cubic feet, has a sampling error of ± 2.28 percent (± 135.5 million cubic feet). The growing-stock volume from a 100-percent inventory would be expected to fall between 5,807.4 million and 6,078.4 million cubic feet ($5,942.9 \pm 135.5$), there being a one in three chance that this is not the case.

As survey data are broken down into sections smaller than State totals, sampling error increases. For example, the sampling error for timberland area in a county is higher than that for total timberland area in the State. The sampling error for estimated area of forest and timberland, volume, average annual net growth, and average annual removals of growing stock and sawtimber at the county and unit levels are presented in table 56. To estimate sampling error for other estimates smaller than State totals, use the following formula:

$$E = \frac{(\text{SE}) \sqrt{(\text{State total volume or area})}}{\sqrt{(\text{Volume or area smaller than State total})}}$$

Where:

E = Sampling error in percent.

SE = State total sampling error for volume or area.

For example, to compute the sampling error on the area of timberland in the maple-beech type for the State, proceed as follows:

- 1) Total statewide area of maple/beech type = 803.3 thousand acres.
- 2) Total statewide area of all timberland = 4,087.0 thousand acres.
- 3) The State total sampling error for timberland area = 1.61 percent.
- 4) Using the above formula:

$$E = \frac{0.0161 \sqrt{4,087.0}}{\sqrt{803.3}}$$

E = 0.0363 or 3.6 percent sampling error for the maple-beech forest type.

The sampling error within a county depends primarily on the county size and the variability of the resource within the county. The more heavily forested counties in the State have sampling errors of between 5 and 15 percent for estimates of timberland area and between 5 and 20 percent for estimates of growing-stock volume. In counties where timberland area is less than 30,000 acres, the sampling errors will generally exceed 20 percent for timberland area and 30 percent for growing-stock volume. Because of the relatively high sampling error, counties with less than 30,000 acres of timberland were combined into county groups.

COMPARING THE FOURTH INVENTORY OF ILLINOIS WITH THE THIRD INVENTORY

A new volume estimation procedure was used to compute the 1998 volumes and to recompute the 1985 volume. Although the adjustment will differ by Survey Unit and species, the recomputed 1985 growing-stock and sawtimber volumes will generally be somewhat less than those shown in the 1985 report. The recomputed volume is 10.7 percent less than what was reported in the 1985 report for sawtimber and 2.6 percent less for growing stock.

A new algorithm was used in 1998 to assign forest type and stand-size class to each condition observed on a plot. This algorithm is being used nationwide by FIA to provide consistency from State to State. It was also used to reassign the forest type and stand-size class of every plot measured in the 1985 inventory so that changes in forest type and stand-size class would reflect actual changes in the forest and not changes due to a change in algorithms. The list of recognized forest types, grouping of these forest types for reporting purposes, equations used to assign stocking values to individual trees, definition of nonstocked, and names given to the forest types changed with the new algorithms. The current definition of nonstocked is stands with a stocking value of less than 10 percent for all live trees.

The basic building block for estimating forest area and timber volume has been changed from the Survey Unit to the county or county

group. In the past, the statistics were developed at the Unit level and prorated back to the county on the basis of photo-interpretation points. Direct development of county-level data helps users interested in more precise local data, but can make data comparisons with past estimates misleading. For example, the 1985 inventory showed 15.1 thousand acres of white pine in the Prairie Unit. The 15.1 thousand acres were shown to occur in 50 of the 60 counties in the Unit (table 12, Raile and Leatherberry 1988) because area of timberland for each forest type was prorated back to each county. In this 1998 publication, we estimate that the total area of white pine in the Prairie Unit is 27.8 thousand acres (all in plantations), and table 3 shows that these acres occur in 8 of the 34 county groups. Survey Unit level comparisons of change between inventories are valid so the 12 thousand acre increase in white pine between 1985 and 1998 in the Prairie Unit is a valid estimate of the change that occurred across the entire Unit. However, it is not valid to estimate change at the county level; a statement such as white pine timberland increased in 7 county groups and disappeared from 40 other counties would not be valid because of the way the 1985 estimates were prorated to the county level.

SURVEY PROCEDURES

The 1998 Illinois survey used a two-phase sample for stratification that remeasured inventory plots from the 1985 inventory and used a growth model in the estimation of current conditions and change over time. Two-phase sampling, also called double sampling, consists of a phase-one sample to estimate area by strata and a phase-two sample to estimate the average value of parameters of interest within these strata. The estimated population total is the sum across all strata of the estimated strata area times the estimated mean.

Phase-one and phase-two plots were placed systematically across the entire State without regard to any particular land characteristics. All lands (forest, nonforest, water, marsh, agricultural, privately owned land, and public lands...) have the same probability of being sampled under this inventory system. The only land that could not be sampled was private land where field personnel could not

obtain permission from the owner of the land to measure a phase-two field plot. These denied-access plots were rare in Illinois (about 1 percent of the total forest plots statewide), and the methods used in the preparation of this report make the necessary adjustments to the estimates to account for denied-access plots.

New plots were only established to replace 1985 plots that could not be remeasured. These new plots were established as near as possible to the original plot. The growth model used in the Illinois survey design was the Central States Stand and Tree Evaluation and Modeling System (STEMS) (Miner *et al.* 1988). Because of the remeasurement nature of the 1998 inventory, procedures for both the 1985 and 1998 inventories are discussed.

Phase-One Stratification

1985 Photo Plot Sampling of Aerial Photographs

In the 1985 inventory, the aerial photographs were assembled into township mosaics, and a systematic grid of 121 one-acre photo plots (each plot representing approximately 190.4 acres) was overlaid on each township mosaic. Each of these photo plots was examined by aerial photo interpretation specialists and classified stereoscopically based on land use, forest type, and stand-size density. A total of 184,815 photo plots formed the basis for the 1985 stratification. From these photo plots, a systematic sample of 10,847 plots were selected as ground plots (without regard to their aerial photo classification) and further examined by survey crews to verify the classification and to take further measurements. Of the ground plots, 1,209 plots were on forest land and the rest were on nonforest land or water. These 1985 ground plots formed the basis for the remeasured ground plots in the 1998 inventory.

1998 Computer-assisted Classification of Satellite Images

Between inventories, FIA changed its phase-one methods. Current inventories use a computer-assisted classification of LandSat Thematic Mapper satellite imagery. Image classification was conducted by Illinois State University as part of the Gap Analysis Program (GAP). The purpose of GAP (a nationwide

multiagency cooperative program) is to provide broad geographic information on the status of ordinary species and their habitats. FIA used the GAP classifications to form two initial strata: forest and nonforest (table C). Pixels within 60 m (2 pixel widths) of a forest/nonforest edge formed two additional strata: forest/nonforest and nonforest/forest. Forest pixels within 2 pixels of a nonforest pixel (in any direction) were classified forest/nonforest, and nonforest pixels within 2 pixels of a forest pixel were classified nonforest/forest. An overlay of all National Forest land ownership was used to identify all lands owned by the Shawnee National Forest. These National Forest lands were treated as a single stratum. Stratification and estimation were conducted at the county or county group level. In a few counties, the forest and forest/nonforest strata were combined because there were fewer than five ground plots in one of these strata. Final estimation of area by strata was based on these five strata: forest, forest/nonforest, nonforest/forest, nonforest, and National Forest land (table C).

Table C.—*Satellite image pixel classification, 1998 Illinois inventory*

Estimation strata	Total pixels
National Forest	1,335,799
Forest	11,450,064
Forest/Nonforest	12,462,762
Nonforest/Forest	24,001,477
Nonforest	<u>130,424,402</u>
All classes	179,674,504

In the 1985 inventory, the stratification was completed by interpretation of the photo plots. The move to GAP satellite imagery changed FIA's phase-one sample from being based on one photo plot every 190.4 acres to a sample based on a classified pixel every 0.22 acres. The increased intensity of the phase-one sample greatly improved estimates of the area with each stratum, particularly at the county level. Thus, the stratification used in the 1998 inventory was based on 179.7 million pixels rather than the classification of 184,815 photo plots. Also, because classification was conducted using a computer-assisted algorithm across the entire State, biases in the photo plot sampling method that resulted from

differences in photo quality, age of photography, and experience of the photo interpreter were eliminated and classification was consistent across the entire State.

Phase-Two Ground Plot Measurements

1985 Plot Design

In 1985, plots classified as timberland, wooded pasture, or windbreak (at least 120 feet wide) were measured. Each ground plot consisted of a cluster of 10 subplots systematically located over a 1-acre area. At each subplot, trees 5.0 inches or more in d.b.h. were sampled on a 37.5 Basal Area Factor (BAF) variable-radius plot, and trees less than 5.0 inches d.b.h. were sampled on a 1/300-acre fixed-radius plot. The arrangement of the 10 subplots within the plot was adjusted if any subplot was located in a land use that was different from subplot one. Under the estimation procedures used in this inventory, the entire plot measurement represented a single land classification, and this land classification was determined by subplot one. Thus, if a subplot was located outside of the land classification of subplot one, it was rotated into that land classification. For example, if subplots 1 through 9 were located in a forest land classification and subplot 10 fell in a pasture, subplot 10 was rotated back into the forest land classification. Under this system, subplot one determined the land classification and all 10 subplots measured the resource within this land class. These plots were established, monumented, and measured as part of the 1985 field inventory. Timberland, wooded pasture, and windbreak plots were monumented using metal stakes and permanent paint marks on trees that would facilitate the remeasurement of the plot. Plots on other land uses were monumented with a pinprick on the aerial photograph.

1998 Plot Design

In 1998 phase two, a set of ground plot locations from the 1985 inventory was transferred to the most recent aerial photographs available and overlaid onto the classified satellite imagery. These old plot locations formed the phase-two sample for the 1998 inventory. Phase-two measurement began with careful stereo examination of the plot location on the best available aerial photograph. Any plots that definitely were not forest land (based on

stereo examination) were given a nonforest ground land-use classification and were not sent to the field for measurement unless the plot had been a forest plot in the 1985 inventory, or the plot was so close to a forest edge that part of it could possibly fall in a forest area. If any portion of the plot could possibly include forest land (including reserved forest land, unproductive forest land, and timberland), wooded pasture, or windbreaks (at least 120 feet wide), it was either remeasured or modeled. New plots were established only if the original plot could not be relocated, in which case a new plot was established in what was considered the original plot location.

Measuring ground plots on all forest lands represented a major change between the 1985 and 1998 inventories. In 1985, plots existed on reserved and unproductive forest land (as they did on all nonforest land classes), but only limited information was collected on these plots and the trees were not measured. Under that system, we were able only to report area of reserved and unproductive forest land by forest type, stand age, and ownership class. With the addition of tree measurements on these plots, we are now able to estimate all the attributes normally reported on timberlands for all forest lands, including reserved and unproductive forest lands.

All ground plots were classified as "undisturbed" or "disturbed" by comparing the 1985 and 1998 aerial photography of the plot location. Disturbance here refers to a major change in forest vegetation caused by factors such as harvesting, land-use change, or a major mortality event. All disturbed plots and a one-third sample of the undisturbed plots were remeasured to obtain estimates of current condition and changes since the last inventory. In the remeasurement of the 1985 ground plots, only subplots 1 through 5 were measured. On these five subplots, all trees measured in 1985 were remeasured or otherwise accounted for, and all new trees that should be tallied using the 1985 plot design were identified and measured. These measurements formed the basis for change estimates between the two inventories such as average annual net growth, mortality, and removals.

Two-thirds of the ground plots that were timberland at the time of the 1985 inventory

and determined to be undisturbed until the 1998 inventory were projected to the current time using STEMS. This procedure gave projected estimates of current volume and growth for these undisturbed plots. The comparison of the projected 1985 ground plots (two-thirds of the total sample) and observed values on the remeasured 1985 ground plots (one-third of the total sample) of the undisturbed forest plots provided local calibration data. The calibration data were used to adjust the projected values of the undisturbed plots that were not remeasured. The adjustment procedure is a modified version of the method described by Smith (1986).

The undisturbed timberland plots that were not remeasured played a crucial role in the survey design. These plots were determined to be undisturbed and had conditions that could be simulated by STEMS. The STEMS growth model was used to "grow" the old plot and tree data to produce an estimate of current data. Thus, these plots were treated as ground plots in the estimation of forest area, number of trees, volume, net growth, and mortality even though they were not revisited. The plot record for each modeled plot was sent to the field for verification of current ownership information.

All old plots classified as disturbed were sent to the field for remeasurement to assess and verify changes since the last inventory. Disturbance refers to any change on a plot that can be detected on the aerial photographs and that the STEMS growth processor cannot predict, such as catastrophic mortality, cutting, regenerating stands, and land-use change.

In the 1998 inventory, the new plot design used was based on the Forest Health Monitoring Program (FHM) plot design. The new 1998 design was laid over the 1985 design so that estimates of change could be based on the old plot design and estimates of current conditions could be based on the new plot design.

The overall plot layout for the new design consisted of four subplots spaced 120 feet apart in a triangular arrangement (fig. 16). The center of the new plot was located at the same point as the center of the 1985 plot. All trees less than 5 inches d.b.h. were measured on a 6.8 foot radius (1/300 acre) circular micro-plot located at the center of each of the four subplots. Trees with diameters 5 inches and larger were measured on a 24 foot radius (1/24 acre) circular plot. Each subplot was mapped for forest condition. Subplots were not rotated even if they fell into another condition. Factors that would determine a change in condition from subplot one were changes in forest type, stand-size class, land use, ownership, and density. Each condition that occurred anywhere on one of the subplots was identified, described, and mapped if the condition in total met or exceeded 1 acre in size (the 1-acre minimum size for a condition to be identified could include land off-plot). Each condition was assigned a condition number, and condition information was recorded.

The change in plot design from the 10-point variable-radius plot design used in 1985 to the four-subplot fixed-area plot design used in this inventory is a result of a national decision to use a single plot design for all FIA inventories nationwide. The rationale for and specific

From Subplot Center	120' to subplot center	Azimuth

1	4	240°

Figure 16.—Standard plot layout for the 1998 Illinois inventory.

details of this plot design are discussed in detail in Hahn *et al.* (1995) and other papers in Forest Science Monograph 31. Both plot designs provided estimates of all the resource information reported in FIA publications including estimates of area, volume, biomass, number of trees, growth, removals, mortality, and basal area. Both plot designs sampled trees of all sizes with known probability, a necessary factor in producing unbiased estimates. Both designs provided unbiased estimates of area. A slight bias in the sampling of large trees near forest-nonforest edge was associated with the variable-radius plot design and could bias estimates of volume but not area. This bias, although very small, could not be eliminated under the previous design. The elimination of this bias was one factor in the decision to change plot designs. This change was particularly important in a State like Illinois where much of the forest land is in small scattered woodlots and the amount of forest-nonforest edge relative to forest land is greater than in more heavily forested States.

The variable-radius design used in 1985 sampled larger trees with higher probability and thus provided better estimates (lower sampling errors) for attributes associated with tree size such as volume, biomass, and basal area. The new fixed-area design samples all trees 5 inches d.b.h. and larger with equal probability and thus provides better estimates for attributes such as number of trees that are not associated with tree size. On average, both sample designs measured about the same number of trees 5 inches d.b.h. and larger on each plot (18 sample trees per plot in 1985 and 16 sample trees per plot in 1998), and the observations of the major variables of interest such as total volume, growth, mortality, and removals were measured with somewhat larger

measurement errors but no bias under the new design. The new design provides a better measurement of smaller trees and thus provides more information about regeneration, species diversity, and noncommercial trees.

Another change in plot measurements that came with the 1998 inventory was the determination of the exact plot location of every ground plot in the inventory. For plots that were visited in the field, this was done using a GPS device at plot center. For the nonforest and undisturbed forest plots that were not visited, plot location was determined by transferring the old plot location from the aerial photography to an unclassified, geo-corrected Landsat TM image. Both procedures provided an accurate location that was used to link the ground plots to the classified GAP data used for stratification.

ESTIMATION

The following sections briefly describe the estimation procedures used to produce the resource tables presented in this and other FIA reports as well as the estimates produced by the table generation programs that are available on CD-ROM or over the Internet. The estimation procedures for computing statistics from this sampling design are somewhat complicated by the fact that not all parameters of interest are observed on every plot. For estimation purposes, the inventory is considered as three different samples: one that uses only the plots that were actually remeasured, one that uses the remeasured and updated plots, and one that uses all plots (remeasured, updated, and new plots). Table D summarizes the distribution of all ground plots for the new inventory design by type of plot.

Table D.—Distribution of ground plots for the 1998 inventory of Illinois's forest resources

Ground land-use class	Old plots remeasured	Old plots updated	New plots	Total plots
Timberland	1,106	427	140	1,673
Reserved forest land	31	2	46	79
Nonforest with trees	235	26	28	289
Nonforest without trees	1,946	6,885	444	9,275
Census water	69	122	17	208
Total	3,387	7,462	675	11,524

All estimates from this inventory are based on double sampling for stratification. Cochran (1977) provides a good general presentation of double sampling for stratification, and Loetsch and Haller (1964) provide a more detailed presentation in a forest inventory context. Scott and Bechtold (1995) describe details of the estimation arising from changes in the plot design related to observing more than one condition on a plot.

Current (1998) Area

In double sampling for estimation, each phase-two sample (ground plot) in a stratum is assigned an area equal to the total estimated area in that stratum divided by the number of phase-two samples (ground plots) in the stratum. This assigned area is referred to as the expansion factor for the plot and represents the individual plot's contribution to the estimation of current total area. A typical plot in the 1998 inventory has an expansion factor of about 3.2 thousand acres. This will vary from plot to plot because of the random variability in the sampling process.

The 1998 plot design was used to estimate all 1998 area estimates such as those presented in tables 1-9, 31, and 32. When a ground plot was observed to be entirely within a single condition, the plots' contribution towards the estimated total area of that condition was the plot's total expansion factor. When a plot straddled more than one condition, the expansion factor was allocated to the various conditions in direct proportion to the proportion of the plot that each condition occupied. For example, a plot with an expansion factor of 3.2 thousand acres that was observed to be 50 percent in oak/hickory timberland, 30 percent in maple/beech timberland, and 20 percent in nonforest land would contribute 1.6 thousand acres to the total estimated area of oak-hickory timberland, 960 acres to the total estimated area of maple/beech timberland, and 640 acres to the total estimate of nonforest land. The estimates of current area were based on all ground plots (remeasured, projected, and new) and the five strata defined by the 1998 GAP classification.

The average expansion factor for a plot of 3,200 acres can be used to estimate approximately how many plots contribute to a particular area estimate. This is useful to users

concerned with the significance of an estimate. For example, table 3 reports there are 36.1 thousand acres of timberland in the white pine type statewide. Using the 3.2 thousand acres per plot as an average expansion factor, we would estimate that about the equivalent of 11 plots were observed to be white pine timberland. In actuality, white pine timberland was observed on 13 plots. Of these 13 ground plots, 7 were entirely in the white pine type and the other 6 ground plots were partially in the white pine type. These six plots ranged from having 25 percent of the plot in white pine to having 75 percent of the plot in white pine.

Area Change (1985-1998)

Area change estimates such as those presented in table A were based only on remeasured and projected plots and use the five strata defined by the 1998 GAP classification. New plots were not included in the sample because they did not provide observations from two points in time. Area change estimates were based on the 1985 plot design and its remeasurement, the condition that was found at plot center in both inventories. These estimates thus reflect observations taken at 3,387 permanent points where determinations of land use, forest type, and other condition classifications were made at two different times (1985 and 1998). The average plot expansion factor for change estimation was 3.7 thousand acres, so a plot observed to be timberland in 1985 and nonforest in 1998 represented 3.7 thousand acres that changed from timberland to nonforest.

Volume

Estimates of volume per acre were made from the trees measured or modeled on all ground plots (remeasured, projected, and new) and the five strata defined by the 1998 GAP classification. These estimates came from measurements taken on the new 1998 plot design. Estimates of volume per acre were multiplied by the area estimates to obtain estimates of total volume. Net cubic foot volumes are based on Hahn and Hansen (1991) for use in the Central States. For the Illinois inventory, the merchantable height equation presented in Hahn and Hansen (1991) was used in conjunction with Stone's equation (see Appendix I in Hahn and Hansen 1991) to estimate gross

Diameter (in.)	Volume in board feet		Board feet per cubic foot	
	Doyle	International 1/4 inch	Doyle	International 1/4 inch
6	4	20	0.92	4.59
8	16	40	2.23	5.59
10	36	65	3.38	6.11
12	64	95	4.32	6.42
14	100	135	5.08	5.85
16	144	180	5.69	7.11
18	196	230	6.22	7.30
20	256	290	6.65	7.53
25	441	460	7.47	7.80
30	676	675	8.06	8.05
35	961	925	8.50	8.18
40	1,296	1,220	8.83	8.32

volume. This estimate was then corrected by species for variation in bark and cull volume to yield an estimate of net volume, using the coefficients presented in Hahn and Hansen (1991).

The Forest Service reports all board foot volume in International 1/4 inch rule. In Illinois, the Doyle log rule is commonly used. A comparison of board-foot volumes and board-foot to cubic-foot ratios for International 1/4 inch and Doyle log rules are listed above (Wenger 1984).

To determine the equivalent Doyle rule board-foot contents of a log from the International 1/4 inch rule, use the conversion table from below. For example, a 12-inch diameter log that is 16 feet long has an International 1/4 inch volume of 95 board feet. To convert to Doyle, multiply 95 by 0.67 to obtain 64 board feet, which is the Doyle equivalent for a 12-inch diameter 16-foot log.

Diameter of log small end (in.)	International 1/4 inch rule to Doyle rule conversion factors					
	Length of log in feet					
	8	10	12	14	16	18
8	0.53	0.50	0.48	0.40	0.40	0.40
10	0.60	0.63	0.60	0.56	0.55	0.53
12	0.71	0.73	0.69	0.66	0.67	0.65
14	0.77	0.78	0.75	0.76	0.74	0.72
16	0.85	0.82	0.83	0.81	0.80	0.79
18	0.89	0.87	0.86	0.86	0.85	0.83
20	0.95	0.91	0.91	0.90	0.88	0.87
25	1.00	0.99	0.97	0.97	0.96	0.94
30	1.04	1.03	1.02	1.01	1.00	0.99
35	1.07	1.06	1.05	1.04	1.04	1.03
40	1.09	1.08	1.08	1.07	1.06	1.06

Net Growth, Mortality, and Removals

In this report, major components of changes in timber volume (growth, mortality, and removals) are reported for two different time periods. Average annual change is an estimate of the change that occurred between inventories. Current change is an estimate of the change that occurred in the final year of the inventory. Besides representing different periods in time, the methods used to estimate each component of change were different for the two periods.

Average annual net growth and mortality (1985-1997).—Estimates of average annual net growth and mortality per acre were made from the trees on plots measured in 1985 and then remeasured or modeled in 1998. The five strata defined by the 1998 GAP classification were used for stratification. All estimates of average annual net growth and mortality came from measurements taken using the 1985 plot design.

On remeasured plots, estimates of average annual net growth and mortality per acre came from the remeasured diameters of trees and from observation of trees that died between inventories, using methods presented by VanDeusen *et al.* (1986). Growth and mortality estimates for old undisturbed plots that were updated were derived in the same manner as remeasured plots. The STEMS growth model was adjusted by Survey Unit to meet local conditions, using data from the undisturbed remeasurement plots. As with volume, total growth and mortality estimates were obtained by multiplying the per acre estimates by area expansion factors.

Current net growth and mortality (1997).—Estimates of current net growth and mortality per acre were made from the trees on all ground plots (remeasured, projected, and new) and the new 1998 plot design. The five strata defined by the 1998 GAP classification were used for stratification. Data from every ground plot were projected forward 1-year using the adjusted STEMS model. These 1-year projections were treated as 1-year remeasurements. Thus, current net growth and mortality estimates represent change over a different period (1997 rather than 1985-1997), use more plots (all plots rather than remeasured and projected plots), are based on a different plot design (1998 design rather than the 1985 design), and use a different

method of observation (growth model projections rather than remeasurement and growth model projections) when they are contrasted with average annual net growth and mortality estimates.

Average annual removals (1985-1997).—Estimates of average annual removals per acre were made from the trees on plots measured in 1985 and then remeasured in 1998. The 1985 photo plot sample was used for stratification. All estimates of average annual removals came from measurements taken using the 1985 plot design. New plots and projected plots were not used to estimate average annual removals. These estimates were obtained from trees measured in the last survey and cut or otherwise removed from the timberland base. Because remeasurement plots were a subset of the total ground plots, and not all remeasurement plots had cutting, average annual removals estimates have greater sampling probability of error than volume, net growth, and mortality estimates.

Current removals (1997).—Estimates of current removals were obtained from a mill survey that was independent of the inventory described here. In a mill survey, sawmills, pulp mills, and other primary timber users were sampled and responded to questions relating to the volume, source, and species of wood they received. This information was combined with estimates of logging utilization, land-use change, firewood removals, and other timber harvests to produce the estimates reported. The Illinois Department of Natural Resources-Division of Forestry provided valuable assistance in this effort by surveying all primary wood-using plants in the State. The methods used to estimate current removals are presented in Smith (1991). Because these estimates did not come from the plot measurement data, the procedures described above to obtain these estimates and associated sampling variabilities do not apply and cannot be obtained from the standard plot measurement FIA database. A special Timber Product Output database is maintained and can be used to obtain estimates of removals for any year. This database is described in May (1998).

TREE AND LOG GRADES

Log and tree grades were based on the classification of external characteristics as indicators

of quality. Log grades and or tree grades were taken on every sawtimber-size tree measured on the new 1998 four-point plot. Sawtimber softwood trees were graded for quality and assigned a butt log grade. Sawtimber hardwood trees were graded for quality and assigned a tree grade. The volume yield by log grade or tree grade for this sample was used to distribute the volume of the ungraded trees (those on projected plots) by species group. In previous inventories only a one-third sample of sawtimber trees were graded.

Hardwood sawtimber trees were graded according to Hanks (1976). The best 12-foot section of the lowest 16-foot hardwood log was used for grading. Hardwood sawtimber trees that did not meet minimum tree grade specifications for grades 1 through 3 were assigned grade 4 according to Forest Service standard specifications for hardwood construction logs described by Rast *et al.* (1973).

Softwood sawtimber trees were graded according to specifications described by Ostrander and Brisbin (1971). For all softwoods, the first merchantable 16-foot log, or shorter lengths down to 12 feet, was used for grading.

Hardwood Tree Grade for Factory Lumber ^a

Grade factor	Tree grade 1	Tree grade 2	Tree grade 3
Length of grading zone (feet)	Butt 16	Butt 16	Butt 16
Length of grading section ^b (feet)	Best 12	Best 12	Best 12
D.b.h., minimum (inches)	16 ^c	13	11
D.i.b., minimum at top of grading section (inches)	13 ^c 16 20	11 ^d 12	8
Clear cuttings (on the 3 best faces) ^e			
Length, minimum (feet)	7 5 3	3 3	2
Number on face (maximum)	2	2 3	Unlimited
Yield in face length (minimum)	5/6	4/6	3/6
Cull deduction (including crook and sweep, but excluding shake) maximum within grading section (percent)	9	f	50

^a Hanks (1976)

^b Whenever a 14- or 16-foot section of the butt 16-foot log is better than the best 12-foot section, the grade of the longer section will become the grade of the tree. This longer section, when used, is the basis for determining the grading factors such as diameter and cull deduction.

^c In basswood and ash, d.i.b. at top of grading section must be 12 inches and d.b.h. must be 15 inches.

^d Grade 2 trees can be 10 inches d.i.b. at top of grading section if they otherwise meet surface requirements for small grade 1's.

^e A clear cutting is a portion of a face free of defects, extending the width of the face. A face is one-fourth of the surface of the grading section as divided lengthwise.

^f Fifteen percent crook and sweep or 40 percent total cull deduction are permitted in grade 2 trees, if size and surface of grading section qualify as grade 1. If rot shortens the required clear cuttings to the extent of dropping the butt log to grade 2, do not drop the tree's grade to 3 unless the cull deduction for rot is greater than 40 percent.

Forest Service Standard Specifications for Hardwood Construction Logs ^{a, b}

Position in tree	Butts and uppers
Minimum diameter small end	8 inches
Minimum length without trim	8 feet
Clear cuttings	No requirements
Sweep allowance	$\frac{1}{4}$ th of the diameter at the small end for each 8 feet of length.
Sound surface defects:	
Single knots	Any number, if no one knot has an average diameter above the callus in excess of one-third of the log diameter at point of occurrence.
Whorled knots	Any number, if the sum of knot diameters above the callus does not exceed one-third of the log diameter at point of occurrence.
Holes	Any number, provided none has a diameter over one-third of the log diameter at point of occurrence and none extends more than 3 inches into included timber ^c .
Unsound surface defects:	Same requirements as for sound defects if they extend into included timber. No limit if they do not. Logs must be sound internally.

^a Rast *et al.* (1973).

^b These specifications are minimum for the class. If, from a group of logs, factory logs are selected first, thus leaving only nonfactory logs from which to select construction logs, then the quality range of the construction logs so selected is limited, and the class may be considered a grade. If selection for construction logs is given first priority, it may be necessary to subdivide the class into grades.

^c Included timber is always square, and dimension is judged from small end.

Eastern White Pine Sawlog Grade Specifications ^a

Grading factor	Log grade 1	Log grade 2	Log grade 3	Log grade 4
1. Minimum scaling diameter (inches)	14 ^b	6	6	6
2. Minimum log length (feet)	10 ^c	8	8	8
3. Maximum weevil injury (number)	None	None	2 injuries ^d	No limit
4. Minimum face requirements	Two full length or four 50% ^e length good faces (in addition, log knots on balance of faces shall not exceed size limit of grade 2 logs).	NO GOOD FACES REQUIRED Maximum diameter of log knots on three best faces: SOUND RED KNOTS not to exceed 1/6 scaling diameter and 3" maximum not to exceed 1/3 scaling diameter and 5" maximum OVERGROWN/DEAD/BLACK KNOTS not to exceed 1/12 scaling diameter and 1 1/2" max. not to exceed 1/6 scaling diameter and 2 1/2" max.		Includes all logs not qualifying for No. 3 or better and having at least 1/3 of their gross volume in sound wood suitable for manufacture into standard lumber.
5. Maximum sweep or crook (%)	20	30	40	66 2/3
6. Maximum total scaling deduction (%)	50	50	50	66 2/3

After the tentative grade is established from face examination, the grade will be reduced whenever the following defects are evident:

7. Conks, punk knots, and pine borer damage on bark surface. ^f
 Degrade one grade if present on one face.
 Degrade two grades if present on two faces.
 Degrade three grades if present on three or more faces.
8. Log end defects: red rot, ring shake, heavy stain, and pine borer damage outside the heart center of log. ^f Consider log as having a total of 8 quarters (4 on each end) and degrade as indicated.
 Degrade one grade if present in 2 quarters of log ends.
 Degrade two grades if present in 3 or 4 quarters of log ends.
 Degrade three grades if present in 5 or more quarters of log ends.

a. Ostrander and Brisbin (1971)

b. 12- and 13-inch logs with four full-length good faces are acceptable.

c. 8-foot logs with four full-length good faces are acceptable.

d. 8-foot Number 3 logs limited to one weevil injury.

e. Minimum 50% length good face must be at least 6 feet.

f. Factors 7 and 8 are not cumulative (total degrade based on more serious of the two). No log is to be degraded below grade 4 if net scale is at least one-third of gross scale.

Log Grades for All Other Softwood Logs

Grade 1

1. Trees must be 16 inches in diameter or larger, grading section 12 feet in length or longer, and with deduction for defect not over 30 percent of gross scale.
2. Trees must be at least 75 percent clear on each of three faces.
3. All knots outside clear cutting must be sound and not more than 2-1/2 inches in size.

Grade 2

1. Trees must be 12 inches in diameter or larger, grading section 12 feet in length or longer, and with a net scale after deduction for defect of at least 50 percent of the gross scale deducted for defect.
2. Trees must be at least 50 percent clear on each of three faces or 75 percent clear on two faces.

Grade 3

1. Trees must be 6 inches in diameter or larger, grading section 12 feet in length or longer, and with a net scale after deduction for defect of at least 50 percent of the gross contents of the log.

Note: Diameters are diameter inside bark at small end of grading section.
Percent clear refers to percent clear in one continuous section.

METRIC EQUIVALENTS

1 acre = 4,046.86 square meters or 0.405 hectare.
1,000 acres = 405 hectares.
1 cubic foot = 0.0283 cubic meter.
1 foot = 30.48 centimeters or 0.3048 meter.
1 inch = 25.4 millimeters, 2.54 centimeters, or 0.0254 meter.
1 pound = 0.454 kilograms.
1 ton = 0.907 metric ton.
1 foot³/acre = 0.07 m³/hectare.

DEFINITION OF TERMS

Average annual mortality of growing

stock.—The average cubic foot volume of sound wood in growing-stock trees that died in one year. Average annual mortality is the average for the years between inventories (1985 to 1997 in this report).

Average annual mortality of sawtimber.—

The average board foot volume of sound wood in sawtimber trees that died in one year. Average annual mortality is the average for the years between inventories (1985 to 1997 in this report).

Average annual removals from growing

stock.—The average net growing-stock volume in growing-stock trees removed annually for roundwood forest products, in addition to the volume of logging residues, and the volume of other removals. Average annual removals of growing stock are the average for the years between inventories (1985 to 1997 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in the Appendix).

Average annual removals from sawtimber.—

The average net board foot sawtimber volume of live sawtimber trees removed annually for roundwood forest products, in addition to the volume of logging residues, and the volume of other removals. Average annual removals of sawtimber are the average for the years between inventories (1985 to 1997 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in the Appendix).

Average annual net growth of growing

stock.—The annual change in cubic foot volume of sound wood in live sawtimber and poletimber trees, and the total volume of trees entering these classes through in-growth, less volume losses resulting from natural causes. Average annual net growth of growing stock is the average for the years between inventories (1985 to 1997 in this report).

Average annual net growth of sawtimber.—

The annual change in the board foot volume of live sawtimber trees, and the total volume of trees reaching sawtimber size, less volume losses resulting from natural causes. Average annual net growth of sawtimber is the average for the years between inventories (1985 to 1997 in this report).

Basal area.—Tree area in square feet of the cross section at breast height of a single tree. When the basal areas of all trees in a stand are summed, the result is usually expressed as square feet of basal area per acre.

Biomass.—The aboveground volume of all live trees (including bark but excluding foliage) reported in green tons (i.e., green weight). Biomass has four components:

Bole.—Biomass of a tree from 1 foot above the ground to a 4-inch top outside bark.

Tops and limbs.—Total biomass of tree from a 1-foot stump minus the bole.

1- to 5-inch trees.—Total aboveground biomass of a tree from 1 to 5 inches in diameter at breast height.

Stump.—Biomass of a tree 5 inches d.b.h. and larger from the ground to a height of 1 foot.

Bolts.—Roundwood logs of less than 8 feet in length that are converted into shingles, cooperage stock, dimension stock, blocks,

blanks, excelsior, etc. No minimum diameter limits. Does not include logs used for the manufacture of pulp or veneer.

Commercial species.—Tree species presently or prospectively suitable for industrial wood products. (Note: Excludes species of typically small size, poor form, or inferior quality such as hophornbeam, Osage-orange, and redbud.)

Cord.—One standard cord is 128 cubic feet of stacked wood, including bark and air space. Cubic feet can be converted to solid wood standard cords by dividing by 79.

Corporate.—Lands owned by a private corporation not in the business of operating primary wood-using plants.

County and municipal land.—Land owned by counties and local public agencies or municipalities, or land leased to these governmental units for 50 years or more.

Cropland.—Land under cultivation within the last 24 months; including cropland harvested, crop failures, cultivated summer fallow, idle cropland used only for pasture, orchards, active Christmas tree plantations indicated by annual shearing, nurseries, and land in soil improvement crops, but excluding land cultivated in developing improved pasture.

Cull.—Portions of a tree that are unusable for industrial wood products because of rot, missing or dead material, form, or other defect.

Current annual net growth of growing stock.—The annual change in volume of sound wood in live sawtimber and poletimber trees, and the total volume of trees entering these classes through in-growth, less volume losses resulting from natural causes, reported for a single year (1997 in this report). Current net growth is based on an estimate of the current annual increment of each growing-stock tree in the inventory.

Current annual net growth of sawtimber.—The annual change in the volume of live sawtimber trees, and the total volume of trees reaching sawtimber size, less volume

losses resulting from natural causes, reported for a single year (1997 in this report). Current net growth is based on an estimate of the current annual increment of each growing-stock tree in the inventory.

Current annual removals from growing stock.—The current net growing-stock volume in growing-stock trees removed annually for roundwood forest products, in addition to the volume of logging residues, and the volume of other removals. Current annual removals of growing stock are reported for a single year (1997 in this report); they are based on a survey of primary wood processing mills to determine removals for products and on information from remeasurement plots (see Survey Procedures in the Appendix) to determine removals due to land-use change.

Current annual removals from sawtimber.—The current net board foot sawtimber volume of live sawtimber trees removed annually for roundwood forest products, in addition to the volume of logging residues, and the volume of other removals. Current annual removals of sawtimber are reported for a single year (1997 in this report); they are based on a survey of primary wood processing mills to determine removals for products and on information from remeasurement plots (see Survey Procedures in the Appendix) to determine removals due to land use change.

Diameter class.—A classification of trees based on diameter outside bark, measured at breast height 4.5 feet above the ground. (Note: d.b.h. is the common abbreviation for diameter at breast height.) Two-inch diameter classes are commonly used in Forest Inventory and Analysis, with the even inch the approximate midpoint for a class. For example, the 6-inch class includes trees 5.0 through 6.9 inches d.b.h.

Diameter at breast height (d.b.h.).—The outside bark diameter at 4.5 feet (1.37 m) above the forest floor on the uphill side of the tree. For determining breast height, the forest floor includes the duff layer that may be present, but does not include unincorporated woody debris that may rise above the ground line.

Forest industry land.—Land owned by companies or individuals operating primary wood-using plants.

Forest land.—Land at least 10 percent stocked by forest trees of any size, or formerly having had such tree cover, and not currently developed for nonforest use. (Note: Stocking is measured by comparing specified standards with basal area and/or number of trees, age or size, and spacing.) The minimum area for classification of forest land is 1 acre. Roadside, streamside, and windbreak strips of timber must have a crown width of at least 120 feet to qualify as forest land. Unimproved roads and trails or clearings in forest areas shall be classed as forest if less than 120 feet wide. Water bodies (rivers, streams, or lakes) less than 30 feet in width shall be classed as forest. Water bodies more than 30 feet in width are classified as water (See Tree, Land, Timberland, Reserved forest land, Other forest land, Stocking, and Water.)

Forest type.—A classification of forest land based on the species forming a plurality of the live tree stocking. FIA forest type classification is based on the tree species that were found on the plot and a national algorithm with regional modifications. Under this system, a forest condition is initially classified into a forest type group. These forest type groups are defined at a national level and not all forest type groups occur within a State. For example, the aspen-birch type group does not occur in Illinois and therefore does not appear in this report. Within these forest type groups, local (State-specific) forest types are recognized within a State. In some cases, only one local forest type is defined within a forest type group for a State, and in other forest type groups there may be two or more local types recognized within a type group. Table 3 displays the forest type groups and local forest types. The following descriptions of each of the forest type groups and local forest types that were identified in Illinois are based on the algorithms used to classify the conditions. The lists of associated species (species not in the type name that are commonly found growing in the forest type) and other comments are based on the data observed on plots from this inventory.

White-red-jack pine.—Forests in which eastern white pine, red pine, and jack pine, singly or in combination, comprise the plurality of the stocking. Illinois is on the very southern range of this forest type group. The natural ranges of red and jack pine do not extend into Illinois and eastern white pine naturally occurs only in the northern portions of the State.

White pine.—Forests in which eastern white pine comprises a plurality of the stocking. Illinois is on the very southern range of eastern white pine and it rarely predominates stocking in natural stands. The stands classified as white pine in this report were all planted stands including overgrown Christmas tree plantations. Red pine, Scotch pine, and other planted species are common associates in these stands as well as other pioneer species such as eastern redcedar, black cherry, and yellow-poplar that seed in and become established in these plantations.

Loblolly-shortleaf pine.—Forests in which loblolly pine and shortleaf pine, singly or in combination, comprise the plurality of the stocking. Illinois is on the very northern range of this forest type group. The natural range of loblolly pine does not extend into Illinois and shortleaf pine naturally occurs only in the southern portions of the State.

Shortleaf pine.—Forests in which shortleaf pine comprises the plurality of the stocking. The stands classified as shortleaf pine in this report are for the most part planted stands. Yellow-poplar, eastern cottonwood, and black cherry are common associates in these stands after they seed in and become established in these plantations.

Oak-pine.—Forests in which hardwoods, singly or in combination, comprise the plurality of the stocking and where softwoods comprise 25 to 50 percent of the stocking. In Illinois, this may or may not be a natural forest type. Many stands that are classified in this group are on disturbed sites that are in transition or are softwood plantations that have a large hardwood component.

Eastern redcedar.—Forests in which eastern redcedar comprises the plurality of the stocking. These are primarily heavily disturbed sites such as abandoned agricultural land and pastures where eastern redcedar has become established.

Eastern redcedar-hardwood.—Forests in which hardwoods, singly or in combination, comprise the plurality of the stocking and where eastern redcedar comprises 25 to 50 percent of the stocking. In Illinois, the hardwood component of these stands is primarily yellow-poplar, red oak, white oak, hickory, and ash.

Oak-pine.—Forests in which oaks and hickories, singly or in combination, comprise the plurality of the stocking and where pine comprises 25 to 50 percent of the stocking. In Illinois, these can be naturally occurring shortleaf pine-oak stands or pine plantations that have large hardwood components.

Oak-hickory.—Forests in which upland oaks and hickories, singly or in combination, comprise the plurality of the stocking.

Chestnut-scarlet oak.—Forests in which upland oaks and hickories, singly or in combination, comprise the plurality of the stocking, and chestnut oak, scarlet oak, post oak, or blackjack oak comprise at least 50 percent of the total stocking.

White oak-red oak-hickory.—Forests in which upland oaks and hickories, singly or in combination, comprise the plurality of the stocking and they do not meet the stocking criteria for chestnut-scarlet oak. Species commonly associated with this forest type include ash, elm, black cherry, sassafras, black locust, and black walnut.

Oak-gum-cypress.—Forests in which tupelo, blackgum, sweetgum, bottomland oaks, or cypress, singly or in combination, comprise a plurality of the stocking. Species commonly associated with this forest type in Illinois include sycamore, soft maple, black cherry, and elm.

Elm-ash-cottonwood.—Forests in which lowland elm, ash, soft maple, or cottonwood, singly or in combination, comprise a plurality of the stocking.

Elm-ash-soft maple.—Forests in which lowland elm, ash, soft maple, or cottonwood, singly or in combination, comprise a plurality of the stocking. Species commonly associated with the elm-ash-soft maple forest type in Illinois include cottonwood, sycamore, hackberry, boxelder, honeylocust, willow, and river birch.

Maple-beech-birch.—Forests in which hard maple, beech, yellow birch, basswood, upland elm, ash, and soft maple, singly or in combination, comprise a plurality of the stocking. This forest type group is typically found on better upland sites.

Maple-beech.—Forests classified in the maple-beech-birch type group in Illinois. Yellow birch is rare in Illinois and the name maple-beech reflects this fact. Species commonly associated with the maple-beech forest type in Illinois include elm, black walnut, basswood, black cherry, ash, and yellow-poplar.

Nonstocked.—Forest stands that do not meet minimum stocking levels and therefore cannot be assigned a forest stand. These stands are primarily recent clearcuts, or fire or storm-damaged areas where regeneration has not yet been established. Nonforest areas that are converting to forest will not be classified as nonstocked because once they have the minimum stocking necessary to be classified as forest they can also be assigned a forest type.

Growing-stock tree.—A live tree of commercial species that meets specified standards of size, quality, and merchantability. (Note: Excludes rough, rotten, and dead trees.)

Growing-stock volume.—Net volume in cubic feet of growing-stock trees 5.0 inches d.b.h. and over, from 1 foot above the ground to a minimum 4.0-inch top diameter outside bark of the central stem or to the point where the central stem breaks into limbs.

Hard hardwoods.—Hardwood species with an average specific gravity greater than 0.50 such as oaks, hard maple, hickories, and ash.

Hardwoods.—Dicotyledonous trees, usually broad-leaved and deciduous. (See Soft hardwoods and Hard hardwoods.)

Improved pasture.—Land currently improved for grazing by cultivating, seeding, irrigating, or clearing trees or brush and less than 10 percent stocked with trees.

Indian land.—Land held in trust by the United States for tribes or individual Indians.

Industrial wood.—All roundwood products except residential fuelwood.

Land.—(a) *Bureau of the Census.* Dry land and land temporarily or partly covered by water such as marshes, swamps, and river flood plains (omitting tidal flats below mean high tide); streams, sloughs, estuaries, and

canals less than one-eighth of a statute mile wide; and lakes, reservoirs, and ponds less than 40 acres in area.

(b) *Forest Inventory and Analysis*. The same as the Bureau of the Census, except minimum width of streams, etc., is 120 feet and minimum size of lakes, etc., is 1 acre.

Live trees.—Growing-stock, rough, and rotten trees 1.0 inch d.b.h. and larger.

Log grade.—A log classification based on external characteristics as indicators of quality or value. Log grade was assigned to a sample of softwood sawtimber trees throughout the State during the 1998 inventory. Also see Tree grade. (See the Appendix for specific grading factors used.)

Logging residue.—The unused portions of cut trees, plus unused trees killed by logging.

Marsh.—Nonforest land that characteristically supports low, generally herbaceous or shrubby vegetation, and that is intermittently covered with water.

Merchantable.—Refers to a pulpwood or saw-log section that meets pulpwood or saw-log specifications, respectively.

Miscellaneous Federal land.—Federal land other than National Forest and land administered by the Bureau of Land Management or Bureau of Indian Affairs.

National Forest land.—Federal land that has been legally designated as National Forest or purchase units, and other land administered by the USDA Forest Service.

Net volume.—Gross volume less deductions for rot, sweep, or other defect affecting use for timber products.

Noncommercial species.—Tree species of typically small size, poor form, or inferior quality that normally do not develop into trees suitable for industrial wood products.

Nonforest land.—Land that has never supported forests, and land formerly forested where use for timber management is precluded by development for other uses. (Note: Includes areas used for crops, active Christmas tree plantations as indicated by annual shearing, orchards, nurseries, improved

pasture, residential areas, city parks, improved roads of any width and adjoining clearings, powerline clearings of any width, and 1- to 40-acre areas of water classified by the Bureau of the Census as land.) If intermingled in forest areas, unimproved roads and nonforest strips must be more than 120 feet wide and more than 1 acre in area to qualify as nonforest land.

Nonforest land without trees.—Nonforest land with no live trees present.

Nonforest land with trees.—Nonforest land with one or more trees per acre at least 5 inches d.b.h.

Nonstocked land.—Timberland less than 10 percent stocked with all live trees.

Other forest land.—Forest land not capable of producing 20 cubic feet per acre per year of industrial wood crops under natural conditions and not associated with urban or rural development. Many of these sites contain tree species that are not currently utilized for industrial wood production or trees of poor form, small size, or inferior quality that are unfit for most industrial products. Unproductivity may be the result of adverse site conditions such as sterile soil, dry climate, poor drainage, high elevation, and rockiness. This land is not withdrawn from timber utilization.

Other removals.—Growing-stock trees removed but not utilized for products, or trees left standing but “removed” from the timberland classification by land use change. Examples are removals from cultural operations such as timber stand improvement work and land clearing, and the standing volume on land classified originally as timberland but later designated as reserved from timber harvesting (such as a newly established State Park).

Ownership size class.—The amount of timberland owned by one owner, regardless of the number of parcels.

Pasture.—Land presently used for grazing or under cultivation to develop grazing.

Physiographic class.—A measure of soil and water conditions that affect tree growth on a site. The physiographic classes are:

Xeric sites.—Very dry soils where excessive drainage seriously limits both growth and

species occurrence. Example: eastern redcedar barrens.

Xeromesic sites.—Moderately dry soils where excessive drainage limits growth and species occurrence to some extent. Example: dry oak ridge.

Mesic sites.—Deep, well-drained soils. Growth and species occurrence are limited only by climate. Example: well-drained terraces of loamy soil.

Hydromesic sites.—Moderately wet soils where insufficient drainage or infrequent flooding limits growth and species occurrence to some extent. Example: moderately drained bottomland hardwood sites.

Hydric sites.—Very wet sites where excess water seriously limits both growth and species occurrence. Example: frequently flooded river bottoms.

Plant byproducts.—Plant residues used for products such as mulch, pulp chips, and fuelwood.

Plantation.—An artificially reforested area sufficiently productive to qualify as timberland. The planted species is not necessarily predominant. Christmas tree plantations, which are considered cropland, are not included.

Plant residues.—Wood and bark materials generated at manufacturing plants during production of other products.

Poletimber stand.—(See Stand-size class.)

Poletimber tree.—A live tree of commercial species at least 5.0 inches d.b.h., but smaller than sawtimber size.

Potential productivity class.—A classification of forest land in terms of inherent capacity to grow crops of industrial wood. The class identifies the potential growth in merchantable cubic feet/acre/year at culmination of mean annual increment of fully stocked natural stands.

Private individual land.—Privately owned land not owned by forest industry. This class includes the formerly used Farmer and Miscellaneous private classes.

Reserved forest land.—Forest land withdrawn from timber utilization through statute,

administrative regulation, or designation.

Note: historically, Christmas tree plantations were classified as reserved forest land. However, Christmas tree plantations are now classified as cropland.

Rotten tree.—Live trees of commercial species that do not contain at least one 12-foot saw log or two saw logs 8 feet or longer, now or prospectively, and/or do not meet regional specifications for freedom from defect primarily because of rot; that is, when more than 50 percent of the cull volume in a tree is rotten.

Rough tree.—(a) Live trees of commercial species that do not contain at least one merchantable 12-foot saw log or two saw logs 8 feet or longer, now or prospectively, and/or do not meet regional specifications for freedom from defect primarily because of roughness or poor form, and (b) all live trees of noncommercial species.

Roundwood products.—Logs, bolts, or other round sections (including chips from roundwood) cut from trees for industrial or consumer uses. (Note: Includes saw logs, veneer logs, and bolts; cooperage logs and bolts; pulpwood; fuelwood; pilings; poles; posts; hewn ties; mine timbers; and various other round, split, or hewn products.)

Salvable dead tree.—A standing or down dead tree considered merchantable by regional standards.

Sapling.—A live tree 1.0 to 5.0 inches d.b.h.

Sapling-seedling stand.—(See Stand-size class.)

Saw log.—A log meeting minimum standards of diameter, length, and defect, including logs at least 8 feet long, sound and straight and with a minimum diameter outside bark (d.o.b.) for softwoods of 7.0 inches (9.0 inches for hardwoods) or other combinations of size and defect specified by regional standards.

Saw-log portion.—That part of the bole of sawtimber trees between the stump and the saw-log top.

Saw-log top.—The point on the bole of sawtimber trees above which a saw log cannot

be produced. The minimum saw-log top is 7.0 inches d.o.b. for softwoods and 9.0 inches d.o.b. for hardwoods.

Sawtimber stand.—(See Stand-size class.)

Sawtimber tree.—A live tree of commercial species containing at least a 12-foot saw log or two noncontiguous saw logs 8 feet or longer, and meeting regional specifications for freedom from defect. Softwoods must be at least 9.0 inches d.b.h. Hardwoods must be at least 11.0 inches d.b.h.

Sawtimber volume.—Net volume of the saw-log portion of live sawtimber in board feet, International 1/4-inch rule (unless specified otherwise), from stump to a minimum 7.0 inches top d.o.b. for softwoods and a minimum 9.0 inches top d.o.b. for hardwoods.

Seedling.—A live tree less than 1.0 inch d.b.h. that is expected to survive. Only softwood seedlings more than 6 inches tall and hardwood seedlings more than 1 foot tall are counted.

Short-log (rough tree).—A sawtimber-size tree of commercial species that contains at least one merchantable 8- to 11-foot saw log but not a 12-foot saw log.

Shrub.—A woody, perennial plant differing from a perennial herb in its persistent and woody stem(s) and less definitely from a tree in its lower stature and/or the general absence of a well-defined main stem. For this report, shrubs were separated somewhat arbitrarily into tall and low shrubs as follows:

Tall shrubs.—Normally taller than 1.6 to 3.2 feet (0.5 to 1.0 meter).

Low shrubs.—Normally shorter than 1.6 to 3.2 feet (0.5 to 1.0 meter). (Woody perennial vines, such as grape, were included with low shrubs.)

Shrub and tree seedling biomass.—The total aboveground weight of trees less than 1.0 inch in diameter and all shrubs.

Site index.—An expression of forest site quality based on the height of a free-growing dominant or codominant tree of a representative species in the forest type at age 50.

Soft hardwoods.—Hardwood species with an average specific gravity less than 0.50, such as cottonwood, red maple, basswood, and willow.

Softwoods.—Coniferous trees, usually evergreen, having needles or scale-like leaves.

Stand.—A group of trees on a minimum of 1 acre of forest land that is stocked by forest trees of any size.

Stand-age class.—A classification based on age of the main stand. Main stand refers to trees of the dominant forest type and stand-size class.

Stand-size class.—A classification of stocked (see Stocking) forest land based on the size class of live trees on the area; that is, sawtimber, poletimber, or seedlings and saplings.

Sawtimber stands.—Stands with half or more of live tree stocking in sawtimber or poletimber trees, and with sawtimber stocking at least equal to poletimber stocking.

Poletimber stands.—Stands with half or more of live tree stocking in poletimber and/or sawtimber trees, and with poletimber stocking exceeding that of sawtimber.

Sapling-seedling stands.—Stands with more than half of the live tree stocking in saplings and/or seedlings.

State land.—Land owned by the State of Illinois or leased to it for 50 years or more.

Stocking.—The degree of occupancy of land by live trees, measured by basal area and/or the number of trees in a stand by size or age and spacing, compared to the basal area and/or number of trees required to fully utilize the growth potential of the land; that is, the stocking standard. A stocking percent of 100 indicates full utilization of the site and is equivalent to 80 square feet of basal area per acre in trees 5.0 inches d.b.h. and larger. In a stand of trees less than 5 inches d.b.h., a stocking percent of 100 would indicate that the present number of trees is sufficient to produce 80 square feet of basal area per acre when the trees reach 5 inches d.b.h.

Stands are grouped into the following stocking classes:

Overstocked stands.—Stands in which stocking of live trees is 100 percent or more.

Fully stocked stands.—Stands in which stocking of live trees is from 61 to 99 percent.

Medium stocked stands.—Stands in which stocking of live trees is from 36 to 60 percent.

Poorly stocked stands.—Stands in which stocking of live trees is from 10 to 35 percent.

Nonstocked areas.—Timberland on which stocking of live trees is less than 10 percent.

Timber products output.—All timber products cut from roundwood and byproducts of wood manufacturing plants. Roundwood products include logs, bolts, or other round sections cut from growing-stock trees, cull trees, salvable dead trees, trees on nonforest land, noncommercial species, sapling-size trees, and limbwood. Byproducts from primary manufacturing plants include slabs, edging, trimmings, miscuts, sawdust, shavings, veneer cores and clippings, and screenings of pulpmills that are used as pulpwood chips or other products.

Timberland.—Forest land that is producing, or is capable of producing, more than 20 cubic feet per acre per year of industrial wood crops under natural conditions, that is not withdrawn from timber utilization, and that is not associated with urban or rural development. Currently inaccessible and inoperable areas are included. (Timberland was formerly called commercial forest land.)

Tree.—A woody plant usually having one or more erect perennial stems, a stem diameter at breast height of at least 3 inches, a more or less definitely formed crown of foliage, and a height of at least 13 feet at maturity.

Tree biomass.—The total aboveground weight (including the bark but excluding the foliage) of all trees from 1 to 5 inches in d.b.h., and the total aboveground weight (including the bark but excluding the foliage) from a 1-foot stump for trees more than 5 inches in diameter.

Tree grade.—A classification of the lower 16 feet of the bole of standing trees based on external characteristics as indicators of the quality and quantity of lumber that could be produced from the tree. Tree grade was assigned to a sample of hardwood sawtimber trees during the 1998 inventory. Also see Log grade. (See the Appendix for specific grading factors used.)

Tree size class.—A classification of trees based on diameter at breast height, including sawtimber trees, poletimber trees, saplings, and seedlings.

Upper stem portion.—That part of the bole of sawtimber trees above the saw-log top to a minimum top diameter of 4.0 inches d.o.b., or to the point where the central stem breaks into limbs.

Urban and other areas.—Areas within the legal boundaries of cities and towns; suburban areas developed for residential, industrial, or recreational purposes; school yards; cemeteries; roads; railroads; airports; beaches; powerlines and other rights-of-way; or other nonforest land not included in any other specified land use class.

Urban forest land.—Land that would otherwise meet the criteria for timberland, but that is in an urban-suburban area surrounded by commercial, industrial, or residential development and not likely to be managed for the production of industrial wood products on a continuing basis. Wood removed would be for land clearing, fuelwood, or esthetic purposes. Such forest land may be associated with industrial, commercial, residential subdivision, industrial parks, golf course perimeters, airport buffer strips, and public urban parks that qualify as forest land.

Water.—(a) *Bureau of the Census.*—Permanent inland water surfaces, such as lakes, reservoirs, and ponds at least 40 acres in area; and streams, sloughs, estuaries, and canals at least one-eighth of a statute mile wide.

(b) *Noncensus.*—Permanent inland water surfaces, such as lakes, reservoirs, and ponds from 1 to 39.9 acres in area; and streams, sloughs, estuaries, and canals from 120 feet to one-eighth of a statute mile wide.

Wooded pasture.—Improved pasture with more than 10 percent stocking in live trees, but less than 25 percent stocking in growing-stock trees. Area is currently improved for grazing or there is other evidence of grazing.

Wooded strip.—An acre or more of natural continuous forest land that would otherwise meet survey standards for timberland except that it is less than 120 feet wide.

¹ From U.S. Bureau of the Census, 1990.

² Includes 187.9 thousand acres of water according to FIA standards of area classification, but defined by the Bureau of the Census as land.

FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

³ BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

⁴ ChChDeFoLiMaMcMoPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.

⁵ CoDoEd = Coles, Douglas, Edgar Counties.

⁶ CoDuLaWi = Cook, Du Page, Lake, Will Counties.

⁷ GrKeLa = Grundy, Kendall, La Salle Counties.

All table cells without observations in the inventory sample are indicated by --. Cells with observations smaller than the precision reported in the table are shown as zero. Columns and rows may not add to their totals due to rounding. FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

- ¹ BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.
- ² ChChDeFoLiMaMcMoPl = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.
- ³ CoDoEd = Coles, Douglas, Edgar Counties.
- ⁴ CoDuLaWi = Cook, Du Page, Lake, Will Counties.
- ⁵ GrKaLa = Grundy, Kendall, La Salle Counties.

All counties	4,087.0	51.8	39.7	662.5	1,302.7	1,340.3	689.9

All table cells without observations in the inventory sample are indicated by --. Cells with observations smaller than the precision reported in the table are shown as zero. Columns and rows may not add to their totals due to rounding. FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

¹ BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

² ChChDeFoLiMaMcMoPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.

³ CoDoEd = Coles, Douglas, Edgar Counties.

⁴ CoDuLaWi = Cook, Du Page, Lake, Will Counties.

⁵ GrKeLa = Grundy, Kendall, La Salle Counties.

All table cells without observations in the inventory sample are indicated by --. Cells with observations smaller than the precision reported in the table are shown as zero. Columns and rows may not add to their totals due to rounding.

¹ This table is based on the stocking percent of growing-stock trees, rather than that of "live" trees. For this table, to use the definition of stocking found in the Appendix, replace the term "live trees" with "growing-stock trees."

² Area of nonstocked in this table and in table 8 differs from that in other tables in this report because this table includes land stocked only with growing-stock trees, rather than with "live" trees.

FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

³ BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

All table cells without observations in the inventory sample are indicated by --. Cells with observations smaller than the precision reported in the table are shown as zero. Columns and rows may not add to their totals due to rounding.

¹ International 1/4 inch rule.

FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

² BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

³ ChChDeFoLiMaMcMoPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.

⁴ CoDoEd = Coles, Douglas, Edgar Counties.

⁵ CoDuLaWi = Cook, Du Page, Lake, Will Counties.

⁶ GrKeLa = Grundy, Kendall, La Salle Counties.

All table cells without observations in the inventory sample are indicated by --. Cells with observations smaller than the precision reported in the table are shown as zero. Columns and rows may not add to their totals due to rounding.

¹ Doyle rule.

FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

² BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

³ ChChDeFoLiMaMcMoPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.

⁴ CoDoEd = Coles, Douglas, Edgar Counties.

⁵ CoDuLaWi = Cook, Du Page, Lake, Will Counties.

⁶ GrKeLa = Grundy, Kendall, La Salle Counties.

¹ Doyle rule.

FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

² BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

³ ChChDeFoLiMaMcMoPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.

⁴ CoDoEd = Coles, Douglas, Edgar Counties.

⁵ CoDuLaWi = Cook, Du Page, Lake, Will Counties.

⁶ GrKeLa = Grundy, Kendall, La Salle Counties.

FIA standards require at least 30,000 acres of forest land for a county to be reported individually. Counties with less than 30,000 acres of forest land were combined into county groupings. When more than 2 counties were combined, the group name consists of the first two letters of each county in the group.

¹ BoDeKaMc = Boone, De Kalb, Kane, Mc Henry Counties.

² ChChDeFoLiMaMcMoPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, Mc Lean, Moultrie, Piatt Counties.

³ CoDoEd = Coles, Douglas, Edgar Counties.

⁴ CoDuLaWi = Cook, Du Page, Lake, Will Counties.

⁵ GrKeLa = Grundy, Kendall, La Salle Counties.

¹ Sampling error is not calculated when the estimated removals are equal to 0.

BoDeKaMc = Boone, DeKalb, Kane, and McHenry Counties.

CaCiDeFoLiMaMcPi = Champaign, Christian, Dewitt, Ford, Livingston, Macon, McLean, Moultrie, and Piatt Counties.

CoDoEg = Coles, Douglas, and Edgar Counties.

CoDuLaWi = Cook, DuPage, Lake, and Will Counties.

GrKeLa = Grundy, Kendall, and LaSalle Counties.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, and marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 14th and Independence Avenue, SW, Washington, DC 20250-9410, or call (202) 720-5964 (voice or TDD). USDA is an equal opportunity provider and employer.

Schmidt, Thomas L.; Hansen, Mark H.; Solomakos, James A.

2000. **Illinois' forests in 1998**. Resour. Bull. NC-198. St. Paul, MN:
U.S. Department of Agriculture, Forest Service, North Central
Research Station. 133 p.

The fourth inventory of Illinois' forests reports 35.6 million acres of land, of which 4.3 million acres are forested. This bulletin contains detailed tables of area, volume, growth, removals, mortality, ownership, and other resource attributes.

KEY WORDS: Forest area, timber volume, net growth, removals, mortality.
